In this work, undoped and iron doped, with different concentrations of dopant (Fe), ZnO thin films were synthesized on glass substrates via a sol–gel spin coating method. The X-ray diffraction results showed that all thin films crystallized under the hexagonal wurtzite structure and exhibited a preferential orientation along the c axis with the maximum crystallite size was found to be about 23 nm for the undoped thin film. UV–Vis diffuse reflectance spectra showed that Fe-doped ZnO exhibited a red-shift of the band-edge and a decrease in band gap energy, as compared to pure ZnO.
